

# Pseudo Random Functions

It does not make much sense to say that any fixed function is pseudorandom. We refer to pseudorandomness of a distribution on functions. An easy way to do this is to consider keyed functions.

A keyed function  $F$  is a two-input function  $F : \{0, 1\}^* \times \{0, 1\}^* \rightarrow \{0, 1\}^*$ , where the first input is called the key and denoted  $k$ , and the second input is just called the input. In general, the key  $k$  will be chosen and then fixed, and we will then be interested in the (single-input) function  $F_k : \{0, 1\}^* \rightarrow \{0, 1\}^*$ . For simplicity, we will assume that  $F$  is length preserving so that the key, input, and output lengths of  $F$  are all the same; i.e., we assume that the function  $F$  is only defined when the key  $k$  and the input  $x$  have the same length, in which case  $|F_k(x)| = |x| = |k|$ . By fixing key  $k$ , we obtain a function  $F$  mapping  $n$ -bit strings to  $n$ -bit strings. We say  $F$  is efficient if there is a deterministic polynomial-time algorithm that computes  $F(k, x)$  given  $k$  and  $x$  as input.

A keyed function  $F$  induces a natural distribution on functions given by choosing a random key  $k \leftarrow \{0, 1\}^n$  and then considering the resulting single-input function  $F_k$ . Intuitively, we call  $F_k$  pseudorandom if the function (for randomly-chosen key  $k$ ) is indistinguishable from a function chosen uniformly at random from the set of all functions having the same domain and range; that is, if no polynomial-time adversary can distinguish whether it is interacting with  $F_k$  (for randomly-chosen key  $k$ ) or  $f$  (where  $f$  is chosen at random from the set of all functions mapping  $n$ -bit strings to  $n$ -bit strings). We wish to construct a keyed function  $F$  such that  $F_k$  (for  $k \leftarrow \{0, 1\}^n$  chosen uniformly at random) is indistinguishable from  $f_n$  (for  $f_n \leftarrow \text{Func}_n$  chosen uniformly at random).
